

Ans1} Race Conditions and Mutual Exclusion

- Race Condition: Occurs when the result of operations depends on the specific, unpredictable order of multiple processes/thread of multiple accessing a shared resource.
- Mutual Exclusion: Solves this by ensuring only one process can enter the Critical Section (the code that manipulates the shared resource) at a time. The first process acquires a lock, performs the complete operation, and releases the lock, forcing the second process to wait.

Ans2} Peterson's Solution vs Semaphores

feature	Peterson's Solution	Semaphores
→ Implementation Complexity.	Low to Moderate. Pure software logic using shared variables	Moderate to High. Requires os Kernel support for waiting queues and system calls (wait() / signal())
→ Hardware Dependency	Low. Primarily dependent on memory consistency/ barriers on modern CPUs	High. Relies on atomic hardware instructions (like Test and Set) for kernel implementation.
→ Scope	limited to mutual exclusion for two processes	General synchronization for N processes.

Ans3} Advantage of Monitors in Multi-core System.

- Monitors automatically encapsulate the shared data and all necessary locking / synchronization logic within a single construct.
- This design ensure that synchronization is centralized and compiler-managed, making it virtually impossible for a programmer to forgot to acquire or release a lock that could lead to deadlocks or subtle errors across

C) Distribute Distributed Algorithm.

The Chandy - Herda - Haas (CHH) Algorithm

- Mechanism : A process waiting for a resource initiates a probe message. If the probe returns to its initiator, a cycle is completed.

Ans 7) Distributed File System Performance

a) Expected File Access Time

$$E[T] = (5ms \times 0.7) + (25ms \times 0.3) = 35ms + 7.5ms = 42.5ms$$

b) Caching Strategy

- suggested strategy : Client-side caching with write-back policy.

→ justification : Remote Access (25ms) is very expensive. While block caching minimizes remote access penalty by data being subsequent reads locally and bypassing network before sending them to the servers.

Ans 8) Checkpoint Optimization for RPO

a) Optimal Fix protocol (max 10 records)

The RPO is 1 second

Type	Count	Checkpoint (ms)
full checkpoint (FC)	2 (at 0s and 10s)	2 * 200 = 400
Incremental (IC)	9 (every 1s in between)	9 * 50 = 450

at 850 ms

Total overhead

b) Explanation of Readonly

- . RPO constraint : An incremental checkpoint (IC) must run every 1 second.

- . Minimal overhead : This maximizes the use of the low cost ICs (50ms) while using high cost FCs (200ms)

multiple cores.

Ans 4) Reader-writer starvation and preemption

- How starvation occurs: In a Readers-Preference situation, if a continuous stream of new readers keeps arriving, they are always given priority over a waiting writer. The writer may be indefinitely delayed because the resource is always busy with reading.

→ Prevention Method: Implement a writer-preference or fair scheduling policy. A writer-preference scheme prevents any new readers from starting once a writer is waiting. After the currently active readers finish, the waiting writers are woken up.

Ans 5) Drawbacks of Eliminating "Hold and Wait".

- Practical Drawback: Local Resource Utilization - A process must hold resources from the start, even if it won't use them until the very end. For that entire duration, the resource sits idle, unavailable to other processes that could be using it, leading to poor system throughput and efficiency.

Ans 6) Distributed deadlock detection simulation.

a) Global Wait-for Graph (WFG)

Combine the local fragments ($P_1 \rightarrow P_2, P_3 \rightarrow P_4, P_2 \rightarrow P_5, P_5 \rightarrow P_6, P_6 \rightarrow P_1$):

$$P_1 \rightarrow P_2 \rightarrow P_5 \rightarrow P_6 \rightarrow P_1 \text{ and } P_3 \rightarrow P_4$$

- b) Deadlock detection and processes involved

→ Deadlock exists: Yes

Reason: There is a cycle in the global WFG
→ Processes Involved: P_1, P_2, P_3 and P_6 .

Ans 9)

E-commerce Case Study

- a) Scheduling & load Balancing
→ Challenge: Heterogeneous load find high synchronization Delay
→ Algorithm: Recliven - Influenced Load sharing
→ Justification: Decentralized approach where under loaded sites work for work, Quality smoothing hash rule spread without centralised latency delay.

b) Fault Tolerance Strategy

- Strategy: Active Replication using Active - Active Group - Redundancy
→ Impact: low RPO: synchronous / near-synchronous data replication ensures minimal / zero data loss.
low RTO: Global Load Balancer immediately routes traffic from the failed region to the healthy, active region, ensuring instant service availability.
